# Review of Probabilities and Basic Statistics 

## 10-701 Recitations

## Overview

- Introduction to Probability Theory
- Random Variables. Independent RVs
- Properties of Common Distributions
- Estimators. Unbiased estimators. Risk
- Conditional Probabilities/Independence
- Bayes Rule and Probabilistic Inference

## Review: the concept of probability

- Sample space $\Omega$ - set of all possible outcomes
- Event $\mathrm{E} \in \Omega-\mathrm{a}$ subset of the sample space
- Probability measure - maps $\Omega$ to unit interval
- "How likely is that event E will occur?"
- Kolmogorov axioms
- $\mathrm{P}(\mathrm{E}) \geq 0$
- $\mathrm{P}(\Omega)=1$
- $\mathrm{P}\left(E_{1} \cup E_{2} \cup \cdots\right)=\sum_{i=1}^{\infty} P\left(E_{i}\right)$

## Reasoning with events

- Venn Diagrams
- $P(A)=\operatorname{Vol}(A) / \operatorname{Vol}(\Omega)$
- Event union and intersection
- $P(A \cup B)=P(A)+P(B)-P(A \cap B)$
- Properties of event union/intersection
- Commutativity: $A \cup B=B \cup A ; A \cap B=B \cap A$
- Associativity: $A \cup(B \cup C)=(A \cup B) \cup C$
- Distributivity: $A \cap(B \cup C)=(A \cap B) \cup(A \cap C)$

## Reasoning with events

- DeMorgan's Laws
- $(A \cup B)^{C}=A^{C} \cap B^{C}$
- $(A \cap B)^{C}=A^{C} \cup B^{C}$
- Proof for law \#l - by double containment
- $(A \cup B)^{C} \subseteq A^{C} \cap B^{C}$
- ...
- $A^{C} \cap B^{C} \subseteq(A \cup B)^{C}$
- ...

## Reasoning with events

- Disjoint (mutually exclusive) events
- $P(A \cap B)=0$
- $P(A \cup B)=P(A)+P(B)$
- examples:
- $A$ and $A^{C}$
- partitions

- NOT the same as independent events
- For instance, successive coin flips

## Partitions

- Partition $S_{1} \ldots S_{n}$
- Events cover sample space $S_{1} \cup \cdots \cup S_{n}=\Omega$
- Events are pairwise disjoint $S_{i} \cap S_{j}=\emptyset$
- Event reconstruction
- $P(A)=\sum_{i=1}^{n} P\left(A \cap S_{i}\right)$
- Boole's inequality
- $P\left(\cup_{i=1}^{\infty} A_{i}\right) \leq \sum_{i=1}^{n} P\left(A_{i}\right)$
- Bayes' Rule
- $P\left(S_{i} \mid A\right)=\frac{P\left(A \mid S_{i}\right) P\left(S_{i}\right)}{\sum_{j=1}^{n} P\left(A \mid S_{j}\right) P\left(S_{j}\right)}$

## Overview

Q Introduction to Probability Theory

- Random Variables. Independent RVs
- Properties of Common Distributions
- Estimators. Unbiased estimators. Risk
- Conditional Probabilities/Independence
- Bayes Rule and Probabilistic Inference

## Random Variables

- Random variable - associates a value to the outcome of a randomized event
- Sample space $\mathcal{X}$ : possible values of rv $X$
- Example: event to random variable

Draw 2 numbers between 1 and 4. Let r.v. $X$ be their sum.

| E | 11 | 12 | 13 | 14 | 21 | 22 | 23 | 24 | 31 | 32 | 33 | 34 | 41 | 42 | 43 | 44 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathrm{X}(\mathrm{E})$ | 2 | 3 | 4 | 5 | 3 | 4 | 5 | 6 | 4 | 5 | 6 | 7 | 5 | 6 | 7 | 8 |

| Induced probability function on $X$ |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| x | 2 | 3 | 4 | 5 | 6 | 7 | 8 |
| $\mathrm{P}(\mathrm{X}=\mathrm{x})$ | $\frac{1}{16}$ | $\frac{2}{16}$ | $\frac{3}{16}$ | $\frac{4}{16}$ | $\frac{3}{16}$ | $\frac{2}{16}$ | $\frac{1}{16}$ |

## Cumulative Distribution Functions

- $F_{X}(x)=P(X \leq x) \forall x \in X$
- The CDF completely determines the probability distribution of an RV
- The function $F(x)$ is a CDF i.i.f
- $\lim _{x \rightarrow-\infty} F(x)=0$ and $\lim _{x \rightarrow \infty} F(x)=1$
- $F(x)$ is a non-decreasing function of $x$
- $F(x)$ is right continuous: $\forall x_{0} \lim _{\substack{x \rightarrow x_{0} \\ x>x_{0}}} F(x)=F\left(x_{0}\right)$

## Identically distributed RVs

- Two random variables $X_{1}$ and $X_{2}$ are identically distributed iif for all sets of values $A$

$$
P\left(X_{1} \in A\right)=P\left(X_{2} \in A\right)
$$

- So that means the variables are equal?
- NO.
- Example: Let's toss a coin 3 times and let $X_{H}$ and $X_{F}$ represent the number of heads/tails respectively
- They have the same distribution but $X_{H}=1-X_{F}$

## Discrete vs. Continuous RVs

- Step CDF
- $X$ is discrete
- Probability mass
- $f_{X}(x)=P(X=x) \forall x$

- Continuous CDF
- $X$ is continuous
- Probability density
e $F_{X}(x)=\int_{-\infty}^{x} f_{X}(t) d t \quad \forall x$

## Interval Probabilities

- Obtained by integrating the area under the curve

- This explains why $\mathrm{P}(\mathrm{X}=\mathrm{x})=0$ for continuous distributions!
$P(X=x) \leq \lim _{\epsilon \rightarrow 0}\left[F_{x}(x)-F_{x}(x-\epsilon)\right]=0$
$\epsilon>0$

## Moments

- Expectations
- The expected value of a function $g$ depending on a r.v. $\mathrm{X} \sim P$ is defined as $E g(X)=\int g(x) P(x) d x$
© $\mathrm{n}^{\text {th }}$ moment of a probability distribution

$$
\mu_{n}=\int x^{n} P(x) d x
$$

- mean $\mu=\mu_{1}$
- $\mathrm{n}^{\text {th }}$ central moment

$$
\mu_{n}^{\prime}=\int(x-\mu)^{n} P(x) d x
$$

- Variance $\sigma^{2}=\mu_{2}{ }^{\prime}$

## Multivariate Distributions

- Example
- Uniformly draw $X$ and $Y$ from the set $\{1,2,3\}^{2}$
- $W=X+Y ; V=|X-Y|$
- Joint
- $P((X, Y) \in A)=\sum_{(x, y) \in A} f(x, y)$
- Marginal

| W V | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathrm{P}_{\mathrm{W}}$ |
| :--- | :--- | :--- | :--- | :--- |
| $\mathbf{2}$ | $1 / 9$ | 0 | 0 | $1 / 9$ |
| $\mathbf{3}$ | 0 | $2 / 9$ | 0 | $2 / 9$ |
| $\mathbf{4}$ | $1 / 9$ | 0 | $2 / 9$ | $3 / 9$ |
| $\mathbf{5}$ | 0 | $2 / 9$ | 0 | $2 / 9$ |
| $\mathbf{6}$ | $1 / 9$ | 0 | 0 | $1 / 9$ |
| $\mathrm{P}_{\mathrm{V}}$ | $3 / 9$ | $4 / 9$ | $2 / 9$ | 1 |

- $f_{Y}(y)=\sum_{x} f(x, y)$
- For independent RVs:
- $f\left(x_{1}, \ldots, x_{n}\right)=f_{X_{1}}\left(x_{1}\right) \ldots f_{X_{n}}\left(x_{n}\right)$

## Overview

Q Introduction to Probability Theory
Q Random Variables. Independent RVs

- Properties of Common Distributions
- Estimators. Unbiased estimators. Risk
- Conditional Probabilities/Independence
- Bayes Rule and Probabilistic Inference

## Bernoulli

- $X=\left\{\begin{array}{l}1 \quad \text { with probability } p \\ 0 \quad \text { with probability } 1-p\end{array} \quad 0 \leq p \leq 1\right.$
- Mean and Variance
- $E X=1 p+0(1-p)=p$
- $\operatorname{Var} X=\left(1-p^{2}\right) p+\left(0-p^{2}\right)(1-p)=p(1-p)$
- MLE: sample mean
- Connections to other distributions:
- If $X_{1} \ldots X_{n} \sim \operatorname{Bern}(p)$ then $\mathrm{Y}=\sum_{i=1}^{n} X_{i}$ is $\operatorname{Binomial}(\mathrm{n}, \mathrm{p})$
- Geometric distribution - the number of Bernoulli trials needed to get one success

## Binomial

- $P(X=x ; n, p)=\binom{n}{x} p^{x}(1-p)^{n-x}$
- Mean and Variance
- $E X=\sum_{x=0}^{n} x\binom{n}{x} p^{x}(1-p)^{n-x}=\ldots=n p$
- $\operatorname{Var} X=n p(1-p)$
- NOTE:

$$
\operatorname{Var} X=E X^{2}-(E X)^{2}
$$

- Sum of Bin is Bin
- Conditionals on Bin are Bin

## Properties of the Normal Distribution

- Operations on normally-distributed variables
- $X_{1}, X_{2} \sim \operatorname{Norm}(0,1)$, then $X_{1} \pm X_{2} \sim N(0,2)$
- $X_{1} / X_{2} \sim \operatorname{Cauchy}(0,1)$
- $X_{1} \sim \operatorname{Norm}\left(\mu_{1}, \sigma_{1}{ }^{2}\right), X_{2} \sim \operatorname{Norm}\left(\mu_{2}, \sigma_{2}{ }^{2}\right)$ and $X_{1} \perp X_{2}$
then $Z=X_{1}+X_{2} \sim \operatorname{Norm}\left(\mu_{1}+\mu_{2}, \sigma_{1}{ }^{2}+\sigma_{2}{ }^{2}\right)$
- If $X, Y \sim N\left(\binom{\mu_{x}}{\mu_{y}},\left(\begin{array}{cc}\sigma_{X}{ }^{2} & \rho \sigma_{X} \sigma_{Y} \\ \rho \sigma_{X} \sigma_{Y} & \sigma_{Y}{ }^{2}\end{array}\right)\right)$, then
$X+Y$ is still normally distributed, the mean is the sum of the means and the variance is
$\sigma_{X+Y}{ }^{2}=\sigma_{X}{ }^{2}+\sigma_{Y}{ }^{2}+2 \rho \sigma_{X} \sigma_{Y}$, where $\rho$ is the correlation

## Overview

Q Introduction to Probability Theory
Q Random Varia.bles. Independent RVs
Q Properties of Common Distributions

- Estimators. Unbiased estimators. Risk
- Conditional Probabilities/Independence
- Bayes Rule and Probabilistic Inference

## Estimating Distribution Parameters

- Let $X_{1} \ldots X_{n}$ be a sample from a distribution parameterized by $\theta$
- How can we estimate
- The mean of the distribution?
- Possible estimator: $\frac{1}{n} \sum_{i=1}^{n} X_{i}$
- The median of the distribution?
- Possible estimator: median $\left(X_{1} \ldots X_{n}\right)$
- The variance of the distribution?
- Possible estimator: $\frac{1}{n} \sum_{i=1}^{n}\left(X_{i}-\bar{X}\right)^{2}$

## Bias-Variance Tradeoff

- When estimating a quantity $\theta$, we evaluate the performance of an estimator by computing its risk - expected value of a loss function
- $\mathrm{R}(\theta, \hat{\theta})=E L(\theta, \hat{\theta})$, where $L$ could be
- Mean Squared Error Loss
- 0/l Loss
- Hinge Loss (used for SVMs)
- Bias-Variance Decomposition: $Y=f(x)+\varepsilon$

$$
\operatorname{Err}(x)=E\left[f(x)-\hat{f}(x)^{2}\right]
$$

$$
=(E[\hat{f}(x)]-f(x))^{2}+E[\hat{f}(x)-E[\hat{f}(x)]]^{2}+{\sigma_{\varepsilon}}^{2}
$$

Bias
Variance

## Overview

Q Introduction to Proba.bility Theory
Q Random Varia.bles. Independent RVs
Q Properties of Common Distributions
Q Estimators. Unbiased estimators. Risk

- Conditional Probabilities/Independence
- Bayes Rule and Probabilistic Inference

## Review: Conditionals

- Conditional Variables
- $P(X \mid Y)=\frac{P(X, Y)}{P(Y)} \quad$ note $\mathrm{X} ; \mathrm{Y}$ is a different r.v.
- Conditional Independence $\quad X \perp Y \mid Z$
- X and Y are cond. independent given Z iif

$$
P((X, Y) \mid Z)=P(X \mid Z) P(Y \mid Z)
$$

- Properties of Conditional Independence
- Symmetry $X \perp Y|Z \Leftrightarrow Y \perp X| Z$
- Decomposition
$X \perp(Y, W)|Z \Rightarrow X \perp Y| Z$
- Weak Union $\quad X \perp(Y, W)|Z \Rightarrow X \perp Y| Z, W$
- Contraction $\quad(X \perp W \mid Z, Y),(X \perp Y \mid Z) \Rightarrow X \perp Y, W \mid Z$

## Overview

Q Introduction to Probability Theory
Q Random Varia.bles. Independent RVs
Q Properties of Common Distributions
Q Estimators. Unıoiased estimators. Risk
Q Conditional Probabilities/Independence

- Bayes Rule and Probabilistic Inference

## Priors and Posteriors

- We've so far introduced the likelihood function
- $P($ Data $\mid \theta)$ - the likelihood of the data given the parameter of the distribution
- $\theta_{M L E}=\operatorname{argmax}_{\theta} P(D a t a \mid \theta)$
- What if not all values of $\theta$ are equally likely?
- $\theta$ itself is distributed according to the prior $P_{\theta}$
- Apply Bayes rule
- $P(\theta \mid$ Data $)=\frac{P(\text { Data } \mid \theta) P(\theta)}{P(\text { Data })}$
- $\theta_{M A P}=\operatorname{argmax}_{\theta} P(\theta \mid$ Data $)=\operatorname{argmax}_{\theta} P($ Data $\mid \theta) P(\theta)$

## NOTituoterers

- If the posterior distributions $P(\theta \mid$ Data $)$ are in the same family as the prior prob. distribution $P_{\theta}$, then the prior and the posterior are called conjugate distributions and $P_{\theta}$ is called conjugate prior
- Some examples

| Likelihood | Conjugate Prior |
| :--- | :--- |
| Bernoulli/Binomial | Beta |
| Poisson | Gamma |
| (MV) Normal with known (co)variance | Normal |
| Exponential | Gamma |
| Multinomial | Dirichlet |

How to compute the parameters of the Posterior?

I'll send a derivation

## Probabilistic Inference

- Problem:You're planning a weekend biking trip with your best friend, Min. Alas, your path to outdoor leisure is strewn with many hurdles. If it happens to rain, your chances of biking reduce to half not counting other factors. Independent of this, Min might be able to bring a tent, the lack of which will only matter if you notice the symptoms of a flu before the trip. Finally, the trip won't happen if your advisor is unhappy with your weekly progress report.

## Probabilistic Inference

- Problem:You're planning a weekend biking trip with your best friend, Min. Your path to outdoor leisure is strewn with many hurdles. If it happens to rain, your chances of biking reduce to half not counting other factors. Independent of this, Min might be able to bring a tent, the lack of which will only matter if you notice the symptoms of a flu before the trip. Finally, the trip won't happen if your advisor is unhappy with your weekly progress report.
- Variables:
- O - the outdoor trip happens
- A-advisor is happy
- R - it rains that day
- T-you have a tent
- F-you show flu symptoms

## Probabilistic Inference

- Problem:You're planning a weekend biking trip with your best friend, Min. Alas, your path to outdoor leisure is strewn with many hurdles. If it happens to rain, your chances of biking reduce to half not counting other factors. Independent of this, Min might be able to bring a tent, the lack of which will only matter if you notice the symptoms of a flu before the trip. Finally, the trip won't happen if your advisor is unhappy with your weekly progress report.
- Variables:
- O - the outdoor trip happens
- A-advisor is happy
- R - it rains that day
- T-you have a tent
- F-you show flu symptoms

## Probabilistic Inference

- How many parameters determine this model?
- $\mathrm{P}(\mathrm{A} \mid \mathrm{O})=>1$ parameter
- $P(R \mid O)=>l$ parameter
- $\mathrm{P}(\mathrm{F}, \mathrm{T} \mid \mathrm{O})=>3$ parameters
- In this problem, the values are given;
- Otherwise, we would have had to estimate them
- Variables:
- O - the outdoor trip happens
- A-advisor is happy
- R - it rains that day
- T-you have a tent
- F-you show flu symptoms

## Probabilistic Inference

- The weather forecast is optimistic, the chances of rain are $20 \%$. You've barely slacked off this week so your advisor is probably happy, let's give it an 80\%. Luckily, you don't seem to have the flu.
- What are the chances that the trip will happen?

Think of how you would do this.
Hint \#l: do the variables F and T influence the result in this case?

Hint \#2: use the fact that the
combinations of values for $A$ and $R$
represent a partition and use one

of the partition formulas we learned
